## Abstract

We present a principled framework for modular web rule bases, called *MWeb*. According to this framework, each predicate defined in a rule base is characterized by its defining reasoning mode, scope, and exporting rule base list. Each predicate used in a rule base is characterized by its requesting reasoning mode and importing rule base list. For valid *MWeb* modular rule bases  $\mathcal{S}$ , the *MWebAS* and *MWebWFS* semantics of each rule base  $s \in \mathcal{S}$  w.r.t.  $\mathcal{S}$  are defined, model-theoretically. These semantics extend the *answer set semantics* (AS) and the *well-founded semantics with explicit negation* (WFSX) on ELPs, respectively, keeping all of their semantical and computational characteristics. Our framework supports: (i) local semantics and different points of view, (ii) local closed-world and open-world assumptions, (iii) scoped negation-as-failure, and (iv) restricted propagation of local inconsistencies. Additionally, it guarantees monotonicity of reasoning, in the case that new rule bases are added to the modular rule base, while the importing rule base list of the predicates of the old rule bases remains the same.

## Introduction

The Semantic Web aims at defining formal languages and corresponding tools, enabling automated processing and reasoning over (meta-)data available from the Web. Logic and knowledge representation play a central role, but the distributed and world-wide nature of the Web brings new interesting research problems. In particular, the widely recognized need of having rules in the Semantic Web (see <http://www.ruleml.org>) has started the discussion on *local closed-world assumptions* (Heflin and Munoz-Avila 2002) and *scoped negation-as-failure* (otherwise, called *scoped default negation*) (RIF ; Kifer et al. 2005). Rule systems often provide for negation, founded on the closed-world assumption of complete information. In the Semantic Web, a rule like “if book1 is not in stock then recommend it” has to be parametrized by the knowledge base (i.e., scope) that is used to search book1 in the stock listings. Intuitively, the term *scoped negation-as-failure* indicates *negation-as-failure*, where the scope of the search failure is well-defined.

Weak (or default) negation is an appropriate rendering of the mechanism of *negation-as-failure* and is non-monotonic.

Strong negation allows the user to express negative knowledge and is monotonic (Baral and Gelfond 1994). Moreover, the combination of weak and strong negation allows the distinction between open and closed predicates, as shown in (Analyti et al. 2008).

The success of the Semantic Web is impossible without any form of modularity, encapsulation, information hiding, and access control. Currently, there is no notion of scope or context in the Semantic Web: all knowledge is global and all kinds of unexpected interactions can occur. In this paper, we propose a framework enabling collaborative reasoning over a set of web rule bases (called *modular rule base*), while support for hidden knowledge is also provided.

In particular, we propose a framework, called *modular web logic framework* (*MWeb*), where users or applications import knowledge about predicates (available on rule bases over the web) into their own rule base. For each predicate defined in a rule base  $s$ , four reasoning modes, `definite`, `open`, `closed`, and `normal` are considered, which indicate, respectively, that weak negation is not accepted at all, only open-world assumptions are accepted, both closed-world and open-world assumptions are accepted, and weak negation is fully accepted. When a user or application imports a predicate  $p$ , he/she may express that certain reasoning modes on  $p$  are not allowed. The producer of a rule base  $s$  might also express that a predicate defined in  $s$  is (i) allowed to be redefined by other rule bases, (ii) allowed only to be used but not redefined by other rule bases, or (iii) is invisible from other rule bases. We call these predicates `global`, `local`, or `internal` to  $s$ , respectively.

We propose two semantics for *MWeb* modular rule bases, called *MWeb answer set semantics* (*MWebAS*) and *MWeb well-founded semantics* (*MWebWFS*). These semantics extend two major semantics for extended logic programs (ELPs), namely *answer set semantics* (AS) (Gelfond and Lifschitz 1990) and *well-founded semantics with explicit negation* (WFSX) (Pereira and Alferes 1992; Alferes, Damásio, and Pereira 1995). We show that, similarly to the corresponding semantics for ELPs, *MWebAS* is more informative than *MWebWFS*. However, *MWebWFS* has better computational properties than *MWebAS*. Our framework supports local semantics and different points of view, local closed-world and open-world assumptions, *scoped negation-as-failure*, and restricted propagation of local inconsistencies. Additionally, it

guarantees monotonicity of reasoning, in the case that new rule bases are added to the modular rule base, while the importing rule base list of the predicates of the old rule bases remains the same.

The rest of the paper is organized as follows: In the next section, we provide a brief overview of our MWeb framework. Then, we formally define modular rule bases. The MWebAS and MWebWFS model-theoretic semantics of modular rule bases are defined in the subsequent section. Then, we provide several properties of MWebAS and MWebWFS. Subsequently, we discuss related work. Conclusions are provided in the concluding section.

## Modularity for Rule Bases on the Web

In this section, we provide a brief overview of our MWeb framework. An *IRI* (*Internationalized Resource Identifier reference*) (Duerst and Suignard 2005) is a Unicode string that is used to provide globally unique names for web resources. For example, given that the namespace prefix `ex` stands for `http://www.example.org/`, the qualified name `ex:Riesling` (which stands for `http://www.example.org/Riesling`) is an IRI reference.

In our framework, *predicates names* are IRI references. Each (MWeb) *rule base*  $s$  is associated with a name  $Nam_s$ , which is also an IRI reference. A *constant* is an IRI reference or an RDF literal (Klyne and Carroll 2004). A *term* is a constant or a variable. In our presentation, variables are prefixed with a question mark symbol (?). Moreover,  $\bar{t}$  denotes a sequence of terms,  $\bar{x}$  denotes a sequence of variables, and  $\bar{c}$  denotes a sequence of constants.

An *atom* is a *simple atom*  $p(t_1, \dots, t_k)$  or a *qualified atom*  $p@Nam_t(t_1, \dots, t_k)$ , where  $p$  is a predicate of arity  $k$ ,  $t_i$ , for  $i = 1, \dots, k$ , are terms and  $Nam_t$  is the name of a rule base  $t$ . An *objective literal* is either an atom  $A$  or the strong negation  $\neg A$  of an atom  $A$ . A *default literal* is the weak negation  $\sim L$  of an objective literal  $L$ . An (MWeb) *rule*  $r$  is a formula of the form:  $L \leftarrow L_1, \dots, L_m, \sim L_{m+1}, \dots, \sim L_n$ , where  $L$  is a simple atom or the strong negation of a simple atom, and  $L_i$  (for  $i \in \{1, \dots, n\}$ ) is an objective literal. We say that  $r$  is *objective*, if no default literal appears in  $r$ . An (MWeb) *logic program*  $P$  is a set of rules. Note that if no qualified atom appears in  $P$  then  $P$  is an ELP. An (MWeb) *modular rule base*  $\mathcal{S}$  is a set of rule bases.

Let  $\mathcal{S}$  be a modular rule base. In addition to a name, each rule base  $s$  is associated with a logic program  $P_s$ . How-

ever, this information is not enough for determining the way knowledge, distributed over the various rule bases of  $\mathcal{S}$ , is integrated. Therefore, each rule base  $s \in \mathcal{S}$  is also associated with an *interface*  $Int_s$  that contains two kinds of declarations: *defines* and *uses* (see Figure 1).

*Defines* declarations determine which predicates  $p$  are defined in  $s$ , as well as their *defining reasoning mode* and *scope* in  $s$ . The user can state the rule bases to which  $s$  is willing to export  $p$ , through the *visible to* clause.

The *defining reasoning mode* of a predicate takes the values *definite*, *open*, *positively closed*, *negatively closed*, or *normal*. In contrast to *normal* predicates, *definite*, *open*, and *closed* predicates impose restrictions on the use of weak negation in their defining rules. It is required that *definite*, *open*, and *closed* predicates do not use *normal* predicates on their definitions. In particular, if a predicate  $p$  is declared *definite* in a rule base  $s$  then  $p$  should be defined by objective rules, only. *Open* and *closed* predicates appearing in the defining rules of  $p$  are interpreted as *definite*. On the other hand, if a predicate  $p$  is declared *open* in  $s$  w.r.t. a predicate  $cxt$  then  $p$  is defined, not only through a set of objective rules, but also through the following rules:  $openRules_s(p) = \{-p(\bar{x}) \leftarrow cxt(\bar{x}), \sim p(\bar{x}), p(\bar{x}) \leftarrow cxt(\bar{x}), \sim \neg p(\bar{x})\}$ . We refer to these rules, as the *contextual OWA rules* of  $p$  in  $s$  and to predicate  $cxt$ , as the *OWA context* of  $p$  in  $s$ . The *contextual OWA rules* of a predicate  $p$  in  $s$  provide a mechanism for making *local OWAs*. If  $p$  is declared *open* in  $s$  without context information then  $p$  is called *freely open* in  $s$ . Additionally:  $openRules_s(p) = \{-p(\bar{x}) \leftarrow \sim p(\bar{x}), p(\bar{x}) \leftarrow \sim \neg p(\bar{x})\}$ . *Closed* predicates appearing in the defining rules of  $p$  are interpreted as *open*.

Similarly, if a predicate  $p$  is declared *positively closed* or *negatively closed* in  $s$  w.r.t. a context  $cxt$  then  $p$  is defined, not only through a set of objective rules, but also through a *positive contextual CWA rule*:  $posClosure_s(p) = \{-p(\bar{x}) \leftarrow cxt(\bar{x}), \sim p(\bar{x})\}$  or a *negative contextual CWA rule*:  $negClosure_s(p) = \{p(\bar{x}) \leftarrow cxt(\bar{x}), \sim \neg p(\bar{x})\}$ . We refer to predicate  $cxt$  as the *CWA context* of  $p$  in  $s$ . The *contextual CWA rules* of a predicate  $p$  in  $s$  provide a mechanism for making *local CWAs*. If  $p$  is declared *positively* or *negatively closed* in  $s$  without context information then  $p$  is called *freely positively* or *freely negatively closed* in  $s$ , respectively. Additionally:  $posClosure_s(p) = \{-p(\bar{x}) \leftarrow \sim p(\bar{x})\}$  and

$negClosure_s(p) = \{p(\bar{x}) \leftarrow \sim \neg p(\bar{x})\}$ , respectively.

Let  $p$  be a predicate, defined in a rule base  $s \in \mathcal{S}$ . If the *scope* of  $p$  is defined as `global` then predicate  $p$  is visible outside  $s$  and can be defined by any other rule base  $s' \in \mathcal{S}$  in global scope, only. The defining reasoning mode of a global predicate must be always definite or open. If the scope of  $p$  is defined as `local` then predicate  $p$  is visible outside  $s$  and can be also defined by another rule base  $s' \in \mathcal{S}$  in internal scope, only. If the scope of a predicate  $p$  defined in a rule base  $s$  is `global` or `local` and the *visible to* clause of its corresponding defines declaration is missing then it is assumed that  $s$  is willing to export  $p$  to any requesting rule base in  $\mathcal{S}$ . Differently to global predicates, no constraint is imposed on the defining reasoning mode of local predicates. Finally, if the scope of  $p$  is defined as `internal` then predicate  $p$  is visible inside  $s$ , only. That is, no other rule base  $s' \in \mathcal{S}$  can import  $p$  from  $s$ . Similarly to local predicates, no constraint is imposed on the defining reasoning mode of internal predicates.

Uses declarations determine which predicates  $p$  are requested by  $s$  and their *requesting reasoning mode* in  $s$ . The user can state the rule bases from which  $s$  requests  $p$ , through the *from* clause. The *requesting reasoning mode* of a used predicate  $p$  in a rule base  $s$  takes the values `definite`, `open`, `closed`, or `normal` and specifies the reasoning mode at which  $s$  is willing to import  $p$ . If the *from* clause of the uses declaration of a predicate  $p$  is missing then  $s$  imports  $p$  from any providing rule base in  $\mathcal{S}$ .

Assume now that a rule base  $s \in \mathcal{S}$  defines a predicate  $p$  in a reasoning mode  $m$  and that another rule base  $s' \in \mathcal{S}$  imports  $p$  from  $s$  in an requesting reasoning mode  $m'$ , different than  $m$ . Then, reasoning modes  $m$  and  $m'$  are combined, and the final reasoning mode that  $s'$  imports  $p$  from  $s$  equals  $least(m, m')$ , where  $definite \leq open \leq closed \leq normal$ . However, an error is caused, if the exporting rule base  $s$  defines  $p$  in normal reasoning mode, and the importing rule base  $s'$  declares that is willing to import  $p$  from  $s$  in definite, open, or closed reasoning mode. This is because, weak negation can freely appear in the definition of  $p$  in  $s$ . Therefore, the definition of  $p$  in  $s$  cannot be translated to a form that satisfies the constraints of the definite, open, or closed reasoning mode.

**Example 1** Consider two rule bases  $s, s' \in \mathcal{S}$  stating, respectively:

```
defines local posClosed p.
uses open p from Nam_s.
```

Thus,  $s$  defines a local predicate  $p$  as freely positively closed and  $s'$  states that is willing to accept  $p$  from  $s$  in open reasoning mode (i.e., the importing reasoning mode of  $p$  in  $s'$  is open). Then, rule base  $s'$  imports  $p$  from  $s$ , as if  $p$  had been declared in  $s$  in open reasoning mode.  $\square$

**Example 2** Consider the MWeb modular rule base  $\mathcal{S} = \{s_1, s_2, s_3, s_4\}$ , shown in Figure 2<sup>1</sup>. Rule base  $s_1$ , with  $Nam_{s_1} = \langle http://europa.eu \rangle$ , defines the

<sup>1</sup>To improve readability, namespace prefixes have been eliminated from the IRIs, representing constants.

list of European Union countries (which does not include Croatia), stating that this list is positively closed w.r.t. the CWA context `geo:Country`. Rule base  $s_2$ , with  $Nam_{s_2} = \langle http://security.int \rangle$ , provides international citizenship information. Additionally, it lists persons suspect for crimes. Rule base  $s_3$ , with  $Nam_{s_3} = \langle http://geography.int \rangle$ , provides geographical information, stating a positively closed list of countries.

Finally, rule base  $s_4$ , with  $Nam_{s_4} = \langle http://gov.countryX \rangle$ , defines the immigration policies of an imaginary country  $X$ , which are supported by the knowledge of the other rule bases in  $\mathcal{S}$ . Note that even though `eu:CountryEU` is defined in  $s_1$ , in positively closed reasoning mode, rule base  $s_4$  imports `eu:CountryEU` from  $s_1$  in open reasoning mode. Furthermore, note that  $s_4$  imports `sec:citizenOf` and `sec:suspect` from  $s_2$  in definite reasoning mode. Even though `sec:citizenOf` is defined in  $s_2$  in local scope, `sec:citizenOf` is also defined internally in  $s_4$  and additional facts about this predicate are stated. This is allowed since the internal information of `sec:citizenOf` in  $s_4$  is not made public. Finally, note the presence of a default qualified literal in the rules of  $P_{s_4}$ .

Note that  $s_2$  is providing confidential information to any requester. Safety can be improved if  $s_2$  specifies the authorized consumers of `sec:citizenOf`, as in:

```
defines global open sec:citizenOf visible to
  <http://gov.countryX>.  $\square$ 
```

## Formalization of Modular Rule Bases

In this section, we formalize MWeb modular rule bases and define their validity. We denote the set of IRI references by  $IRI$  and the set of RDF literals by  $LIT$ . Additionally, we denote the set of variable symbols by  $Var$ . The sets  $Var$ ,  $IRI$ , and  $LIT$  are pairwise disjoint.

An (MWeb) *vocabulary*  $V$  is a triple  $\langle RBase, Pred, Const \rangle$ , where  $RBase \subseteq IRI$  is a set of rule base names,  $Pred \subseteq IRI$  is a set of predicate names, and  $Const \subseteq IRI \cup LIT$  is a set of constant symbols.

Each predicate name  $p \in Pred$  is associated with an arity  $arity(p) \in \mathbb{N}$ . A *term*  $t$  over  $V$  is an element of  $Const \cup Var$ . Predicate names, rule base names, and terms are used for forming atoms and literals, as follows:

Let  $V = \langle RBase, Pred, Const \rangle$  be a vocabulary. An (MWeb) *atom* over  $V$  is a *simple atom*  $p(t_1, \dots, t_n)$  or a *qualified atom*  $p@rbase(t_1, \dots, t_n)$ , where  $p \in Pred$ ,  $rbase \in RBase$ ,  $n = arity(p)$ , and  $t_i$  is a term over  $V$ , for  $i = 1, \dots, n$ .

Let  $V = \langle RBase, Pred, Const \rangle$  be a vocabulary. An *objective literal* over  $V$  is an atom  $A$  or the strong negation  $\neg A$  of an atom  $A$  over  $V$ . A *default literal* over  $V$  is the weak negation  $\sim L$  of an objective literal  $L$  over  $V$ . An (MWeb) *literal* over  $V$  is an objective or a default literal over  $V$ .

We denote the set of objective literals over  $V$  and the set of literals over  $V$  by  $Lit^o(V)$  and  $Lit(V)$ , respectively. Let  $L \in Lit(V)$ . We define  $pred(L) = p$ , where  $p$  is the predicate name appearing in  $L$ . If  $L$  is built from a qualified

Figure 2: An MWeb modular rule base

atom  $p@rbase(\bar{t})$ , we define the *qualifying rule base* of  $L$  as  $qual(L) = rbase$ . Otherwise,  $qual(L)$  is undefined.

Let  $L$  be a qualified literal, we denote by *simple*( $L$ ), the literal  $L$  without  $qual(L)$ , e.g. *simple*( $sec:Suspect@(\text{http://security.int})(?p)$ ) =  $sec:Suspect(?p)$ .

Let  $L \in Lit^o(V)$ , we define  $\neg(\neg L) = L$  and  $\sim(\sim L) = L$ . Additionally, let  $S \subseteq Lit^o(V)$ . We define  $\neg S = \{\neg L \mid L \in S\}$  and  $\sim S = \{\sim L \mid L \in S\}$ .

Based on literals, we define rules and logic programs, as follows:

**Definition 1 (Logic program)** Let  $V = \{RBase, Pred, Const\}$  be a vocabulary. An (MWeb) rule  $r$  over  $V$  is an expression  $L_0 \leftarrow L_1, \dots, L_m, \sim L_{m+1}, \dots, \sim L_n$ , where: (i)  $L_0 \in Lit^o(V)$  and  $L_0$  is a simple literal (i.e.,  $qual(L_0)$  is undefined), (ii)  $L_i \in Lit^o(V) \cup \{t, u\}$ , for  $i = 1, \dots, m$ , and (iii)  $L_i \in Lit^o(V)$ , for  $i = m+1, \dots, n$ . We define  $Head_r = L_0$ ,  $Body_r^+ = \{L_1, \dots, L_m\}$ ,  $Body_r^- = \{L_{m+1}, \dots, L_n\}$ , and  $Body_r = Body_r^+ \cup \sim Body_r^-$ . An (MWeb) logic program over  $V$  is a set of rules over  $V$ .  $\square$

The symbols  $t$  and  $u$  are called *special literals* and represent the truth values true and undefined, respectively.

As we have seen in the previous section, each rule base  $s$  is associated with a name  $Nam_s$ , a logic program  $P_s$ , and an interface  $Int_s$  that includes defines and uses declarations.

**Definition 2 (Rule base)** Let  $V = \langle RBase, Pred, Const \rangle$  be a vocabulary. An (MWeb) rule base  $s$  over  $V$  is a triple  $s = \langle Nam_s, P_s, Int_s \rangle$ , where: (i)  $Nam_s \in RBase$  is the name of  $s$ , (ii)  $P_s$  is a logic program over  $V$ , called the *logic program* of  $s$ , and (iii)  $Int_s = \langle Def_s, Use_s \rangle$  is the interface of  $s$ , where:

- $Def_s$  is a set of tuples  $\langle p, sc, mod, cxt, Exp \rangle$ , where  $p \in Pred$ ,  $sc \in \{gl, lc, int\}$ ,  $mod \in \{d, o, c^+, c^-, n\}$ ,  $cxt \in Pred \cup \{n/a\}$ , and  $Exp \subseteq RBase - \{Nam_s\}$  or  $Exp = \{*\}$ .

We define  $Pred_s^D = \{p \mid \exists \langle p, sc, mod, cxt, Exp \rangle \in Def_s\}$ ,  $scope_s(p) = sc$ ,  $mode_s^D(p) = mod$ ,  $context_s(p) = cxt$ , and  $Export_s(p) = Exp$ .

- $Use_s$  is a set of tuples  $\langle p, mod, Imp \rangle$ , where  $p \in Pred$ ,  $mod \in \{d, o, c, n\}$ , and  $Imp \subseteq RBase - \{Nam_s\}$  or  $Imp = \{*\}$ .

We define  $Pred_s^U = \{p \mid \exists \langle p, mod, Imp \rangle \in Use_s\}$ ,  $mode_s^U(p) = mod$ , and  $Import_s(p) = Imp$ .  $\square$

Let  $s$  be a rule base. We define:  $Pred_s = Pred_s^D \cup Pred_s^U$ . Intuitively, each tuple  $\langle p, sc, mod, cxt, Exp \rangle \in Def_s$  corresponds to a defines declaration of  $s$ , where  $p$  is a predicate defined in  $s$ ,  $sc$  is the scope of  $p$  in  $s$  (i.e., global, local, or internal),  $mod$  is the defining reasoning mode of  $p$  in  $s$  (i.e., definite, open, positively closed, negatively

closed, or normal),  $ctx$  is the context of  $p$  in  $s$  (if defined), and  $Exp$  is the list of rules bases to which  $s$  is willing to export  $p$ . If the *wrt context* clause of the defines declaration is missing then  $ctx = \text{n/a}$ . Additionally, if  $sc = \text{int}$  and the *visible to* clause of the defines declaration is missing then  $Exp = \{\}$ . However, if  $sc \in \{\text{gl}, \text{lc}\}$  and the *visible to* clause of the defines declaration is missing then  $Exp = \{*\}$ . This means that  $s$  is willing to export  $p$  to any requesting rule base. We say that  $p$  is *freely open* (resp. *freely closed*) in  $s$  if  $mode = \text{o}$  (resp.  $mode \in \{\text{c}^+, \text{c}^-\}$ ) and  $ctx = \text{n/a}$ .

Similarly, each tuple  $\langle p, mod, Imp \rangle \in Use_s$  corresponds to a uses declaration of  $s$ , where  $p$  is a predicate requested by  $s$ ,  $mod$  is the requesting reasoning mode of  $p$  in  $s$  (i.e., definite, open, closed, or normal), and  $Imp$  is the list of rules bases from which  $p$  is requested. If the *from* clause of the uses declaration is missing then  $Imp = \{*\}$ . In this case,  $s$  imports  $p$  from any providing rule base.

**Example 3** Consider rule base  $s_1$  of Example 2. Then,  $Def_{s_1} = \{\langle \text{eu:CountryEU}, \text{lc}, \text{c}^+, \text{geo:Country}, \{*\} \rangle\}$  and  $Use_{s_1} = \{\langle \text{geo:Country}, \text{d}, \{\langle \text{http://geography.int} \rangle\} \rangle\}$ .  $\square$

We define<sup>2</sup>:  $|\text{d}| = \text{d}, |\text{o}| = \text{o}, |\text{c}^+| = |\text{c}^-| = \text{c}$ , and  $|\text{n}| = \text{n}$ . Then, we impose the following total order:  $\text{d} \leq \text{o} \leq \text{c} \leq \text{n}$ , called *reasoning mode extension*. Additionally, we impose the following total order on predicate scopes:  $\text{int} \leq \text{lc} \leq \text{gl}$ , called *predicate scope extension*.

**Definition 3 (Valid rule base)** A rule base  $s = \langle Nam_s, P_s, Int_s \rangle$  over a vocabulary  $V = \{RBase, Pred, Const\}$  is *valid* iff:

1. If  $\langle p, sc, mod, ctx, Exp \rangle, \langle p, sc', mod', ctx', Exp' \rangle \in Def_s$  then  $sc = sc', mod = mod', ctx = ctx',$  and  $Exp = Exp'$ .
2. If  $\langle p, mod, Imp \rangle, \langle p, mod', Imp' \rangle \in Use_s$  then  $mod = mod'$  and  $Imp = Imp'$ .
3. For all  $r \in P_s$ :
  - (a)  $pred(Head_r) \in Pred_s^D$ .
  - (b)  $Body_r \cap \{\text{u}\} = \emptyset$ .
  - (c) for all  $L \in Body_r - \{\text{t}\}$ ,  $pred(L) \in Pred_s$ .
4. For all  $\langle p, sc, mod, ctx, Exp \rangle \in Def_s$ :
  - (a) if  $mod \in \{\text{o}, \text{c}^+, \text{c}^-\}$  and  $ctx \in Pred$  then  $ctx \in Pred_s$  and  $arity(ctx) = arity(p)$ ,
  - (b) if  $ctx \in Pred_s^D$  then  $mode_s^D(ctx) \in \{\text{d}\}$ ,
  - (c) if  $ctx \in Pred_s^U$  then  $mode_s^U(ctx) \in \{\text{d}\}$ ,
  - (d) if  $mod \in \{\text{d}, \text{n}\}$  then  $ctx = \text{n/a}$ .
5. If  $p \in Pred_s^D$  and  $scope_s(p) = \text{gl}$  then  $mode_s^D(p) \in \{\text{d}, \text{o}\}$ .
6. If  $p \in Pred_s^D$  and  $scope_s(p) = \text{int}$  then  $Export_s(p) = \{\}$ .

<sup>2</sup>This auxiliary definition is needed, because the defining reasoning modes of a predicate  $p$  are  $\{\text{d}, \text{o}, \text{c}^+, \text{c}^-, \text{n}\}$ , whereas the requesting reasoning modes of a predicate  $p$ , and the reasoning modes of an interpretation of a rule base  $s$  (to be defined later) are  $\{\text{d}, \text{o}, \text{c}, \text{n}\}$ .

7. If  $p \in Pred_s^D \cap Pred_s^U$  then  $mode_s^U(p) \leq |mode_s^D(p)|$ .
8. For all  $r \in P_s$ , and for all  $L \in Body_r$ :
  - if  $qual(L) \in RBase$  then  $qual(L) \in Import_s(pred(L))$  or  $Import_s(pred(L)) = \{*\}$ .
9. For all  $r \in P_s$ , and for all  $L \in Body_r$ :
  - if  $mode_s^D(pred(Head_r)) \neq \text{n}$  then:
    - (a)  $Body_r^- = \{\}$ ,
    - (b) for all  $L \in Body_r^+$ , if  $pred(L) \in Pred_s^D$  then  $mode_s^D(pred(L)) \neq \text{n}$ , and
    - (c) for all  $L \in Body_r^+$ , if  $pred(L) \in Pred_s^U$  then  $mode_s^U(pred(L)) \neq \text{n}$ .  $\square$

Let  $s$  be a valid rule base. Constraint 1 of Definition 3 expresses that for each defined predicate, there should be only one defines declaration in  $s$ . Constraint 2 expresses that for each requested predicate, there should be only one uses declaration in  $s$ . Constraint 3 expresses that for each predicate appearing in the head of a rule  $r \in P_s$ , there should be a corresponding defines declaration. Additionally, the special literal  $\text{u}$  should not appear in the body of any rule  $r \in P_s$ . Further, for each predicate appearing in the body of  $r$ , there should be a corresponding defines or uses declaration. Constraint 4 expresses that each open or closed predicate  $p$ , defined in  $s$ , can be associated with a predicate  $ctx$ . This predicate  $ctx$  should be defined in  $s$  or requested by  $s$  and have the same arity as  $p$ . If  $ctx$  is defined in (resp. requested by)  $s$  then its defining (resp. requesting) reasoning mode should be definite.

Constraint 5 expresses that each global predicate of  $s$  should be defined in definite or open reasoning mode. Constraint 6 expresses that each internal predicate of  $s$  is not visible by other rule bases. Constraint 7 expresses that if a predicate  $p$  is both defined in  $s$  and requested by  $s$  then its defining reasoning mode in  $s$  should extend its requesting reasoning mode in  $s$ . Intuitively, this means that the use of weak negation in the imported definition of  $p$  should satisfy the constraints of the defining reasoning mode of  $p$  in  $s$ .

Constraint 8 expresses that if a qualified literal  $L$  appears in the body of a rule  $r \in P_s$  then rule base  $s$  should request  $pred(L)$  from rule base  $qual(L)$ . Constraint 9 expresses that for each rule  $r \in P_s$ , if the defining reasoning mode of the predicate appearing in  $Head_r$  is restricted (i.e., not normal) then: (i) no default literal should appear in  $Body_r$ , and (ii) the defining (resp. requesting) reasoning mode of each defined (resp. requested) predicate appearing in  $Body_r$  should also be restricted.

**Example 4** Rule bases  $s_1, s_2, s_3$ , and  $s_4$  of Example 2 are valid.

**Definition 4 (Modular rule base)** An (MWeb) *modular rule base*  $\mathcal{S}$  over a vocabulary  $V$  is a set of valid rule bases over  $V$ .  $\square$

Let  $\mathcal{S}$  be a modular rule base,  $s \in \mathcal{S}$ , and  $p \in Pred_s^D$ . We define:

$$Export_s^{\mathcal{S}}(p) = \begin{cases} \{Nam_{s'} \mid s' \in \mathcal{S} - \{s\}\} & \text{if } Export_s(p) = \{*\} \\ Export_s(p) \cap \{Nam_{s'} \mid s' \in \mathcal{S}\} & \text{otherwise} \end{cases}$$

Intuitively,  $Export_s^S(p)$  denotes the rule bases in  $\mathcal{S}$  that  $s$  is willing to export  $p$ . We refer to  $Export_s^S(p)$  as the *exporting rule base list* of  $p$  in  $s$  w.r.t.  $\mathcal{S}$ .

Let  $\mathcal{S}$  be a modular rule base,  $s \in \mathcal{S}$ , and  $p \in Pred_s^U$ . We define:

$$Import_s^S(p) = \begin{cases} ExportingTo_{\mathcal{S}}(p, s) & \text{if } Import_s(p) = \{*\} \\ Import_s(p) \cap ExportingTo_{\mathcal{S}}(p, s) & \text{otherwise} \end{cases}$$

where  $ExportingTo_{\mathcal{S}}(p, s) = \{Nam_{s'} \mid s' \in \mathcal{S}, Nam_s \in Export_{s'}^S(p)\}$ .

Intuitively,  $ExportingTo_{\mathcal{S}}(p, s)$  denotes the rule bases in  $\mathcal{S}$  that are willing to export  $p$  to  $s$ . Note that for the modular rule base  $\mathcal{S}$  of Example 2,  $ExportingTo_{\mathcal{S}}(\text{sec:citizenOf}, s_4) = \{s_2\}$ . Additionally,  $Import_s^S(p)$  denotes the rule bases in  $\mathcal{S}$  from which  $s$  imports  $p$ . We refer to  $Import_s^S(p)$  as the *importing rule base list* of  $p$  in  $s$  w.r.t.  $\mathcal{S}$ . Note that: for all  $p \in Pred_s^D$ ,  $Nam_s \notin Export_s^S(p)$ . Additionally, for all  $p \in Pred_s^U$ ,  $Nam_s \notin Import_s^S(p)$ .

**Example 5** Consider the modular rule base  $\mathcal{S} = \{s_1, s_2, s_3, s_4\}$  of Example 2. It holds,  $Export_{s_2}^S(\text{sec:citizenOf}) = \{s_1, s_3, s_4\}$ , while  $Export_{s_2}(\text{sec:citizenOf}) = \{*\}$ . Additionally, it holds  $Import_{s_4}^S(\text{sec:citizenOf}) = \{s_2\}$ .  $\square$

**Definition 5 (Valid modular rule base)** A modular rule base  $\mathcal{S}$  is *valid* iff:

1. If  $s \in \mathcal{S}$  then  $s$  is a valid rule base.
2. If  $s, s' \in \mathcal{S}$  and  $s \neq s'$  then  $Nam_s \neq Nam_{s'}$ .
3. For all  $s, s' \in \mathcal{S}$  s.t.  $s \neq s'$ , and for all  $p \in Pred_s^D$ :  
if  $scope_s(p) = \text{int}$  then  $p \notin Pred_{s'}^U$  or  $Nam_s \notin Import_{s'}^S(p)$ .
4. For all  $s, s' \in \mathcal{S}$  s.t.  $s \neq s'$ , and for all  $p \in Pred_s^D \cap Pred_{s'}^D$ , s.t.  $Nam_s \in Import_{s'}^S(p)$ :  
if  $mode_s^D(p) = \mathbf{n}$  then  $mode_{s'}^U(p) = \mathbf{n}$ .
5. For all  $s, s' \in \mathcal{S}$  s.t.  $s \neq s'$ , and for all  $p \in Pred_s^D \cap Pred_{s'}^D$ :  
if  $scope_s(p) = \text{lc}$  then  $scope_{s'}(p) = \text{int}$ .
6. For all  $s, s' \in \mathcal{S}$  s.t.  $s \neq s'$ , and for all  $p \in Pred_s^D \cap Pred_{s'}^D$ :  
if  $scope_s(p) = \text{gl}$  then  $scope_{s'}(p) = \text{int}$  or  $scope_{s'}(p) = \text{gl}$ .
7. If  $s \in \mathcal{S}$  and  $p \in Pred_s^U$  then  $Import_s(p) = \{*\}$  or  $Import_s(p) \subseteq ExportingTo_{\mathcal{S}}(p, s)$ .  $\square$

Let  $\mathcal{S}$  be a valid modular rule base. Constraint 1 of Definition 5 expresses that each rule base in  $\mathcal{S}$  should be a valid rule base. Constraint 2 expresses that distinct rule bases in  $\mathcal{S}$  should have distinct names. Constraint 3 expresses that if a rule base  $s \in \mathcal{S}$  defines internally a predicate  $p$  then another rule base  $s' \in \mathcal{S}$  cannot request  $p$  from  $s$ . Constraint 4 expresses that if a predicate  $p$  is defined in a rule base  $s \in \mathcal{S}$  in normal reasoning mode and requested by another rule base  $s' \in \mathcal{S}$  from  $s$  then its requesting reasoning mode in  $s'$  should also be normal. This is because, the use of weak negation in the definition of  $p$  in  $s$  is unrestricted.

Constraint 5 expresses that if a predicate  $p$  is defined in a rule base  $s \in \mathcal{S}$  in local scope then it can be defined by another rule base  $s' \in \mathcal{S}$  only in internal scope. This is because internal predicates are invisible to other rule bases. Constraint 6 expresses that if a predicate  $p$  is defined in a rule base  $s \in \mathcal{S}$  in global scope then it can be defined by another rule base  $s' \in \mathcal{S}$  only in global or internal scope. Constraint 7 expresses that if a rule base  $s \in \mathcal{S}$  requests a predicate  $p$  from a *specific* rule base  $s'$  then  $s'$  should be a rule base of  $\mathcal{S}$  that defines  $p$  and is willing to export  $p$  to  $s$ . That is,  $Import_s(p) = \{*\}$  or  $Import_s(p) = Import_s^S(p)$ .

**Example 6** Modular rule base  $\mathcal{S}$  of Example 2 is valid.  $\square$

**Convention:** In this work, we consider valid modular rule bases, only.

## Model-theoretic Semantics for Modular Rule Bases

In this section, we propose the MWeb *answer set semantics* (MWebAS) and the MWeb *well-founded semantics* (MWebWFS) for modular rule bases. We will show that these semantics extend the answer set semantics (AS) and the well-founded semantics with explicit negation (WFSX) on ELPs, respectively. First, we define the normal and extended interpretations of a modular rule base.

Let  $\mathcal{S} = \{s_1, \dots, s_n\}$  be a modular rule base. The *Herbrand universe* of  $\mathcal{S}$  is defined as:  $HU_{\mathcal{S}} = HU_{s_1} \cup \dots \cup HU_{s_n}$ , where  $HU_{s_i}$  (for  $i = 1, \dots, n$ ) is the set of constants appearing in  $P_{s_i}$ .

Let  $\mathcal{S}$  be a modular rule base over a vocabulary  $V = \{RBase, Pred, Const\}$ . Let  $p \in Pred$ ,  $n = \text{arity}(p)$ , and  $rbase \in RBase$ . We denote by  $[p]_{\mathcal{S}}$  the set of literals  $p(t_1, \dots, t_n)$  and  $\neg p(t_1, \dots, t_n)$ , where  $t_i \in HU_{\mathcal{S}}$ , for  $i = 1, \dots, n$ . Additionally, we denote by  $[p@rbase]_{\mathcal{S}}$  the set of literals  $p@rbase(t_1, \dots, t_n)$  and  $\neg p@rbase(t_1, \dots, t_n)$ , where  $t_i \in HU_{\mathcal{S}}$ , for  $i = 1, \dots, n$ .

Let  $\mathcal{S}$  be a modular rule base and let  $s \in \mathcal{S}$ . The *Herbrand base* of  $s$  w.r.t.  $\mathcal{S}$  is defined as:  $HB_s^{\mathcal{S}} = \{[p]_{\mathcal{S}} \mid p \in Pred_s\} \cup \{[p@rbase]_{\mathcal{S}} \mid p \in Pred_s^U, rbase \in Import_s^S(p)\}$ .

Let  $\mathcal{S}$  be a modular rule base and let  $s \in \mathcal{S}$ . A *simple normal interpretation* of  $s$  w.r.t.  $\mathcal{S}$  is a set  $I \subseteq HB_s^{\mathcal{S}}$  s.t.  $I \cap \neg I = \emptyset$  (*consistency*) or  $I = HB_s^{\mathcal{S}}$ . If  $I = HB_s^{\mathcal{S}}$  then  $I$  is called *inconsistent*. Otherwise,  $I$  is called *consistent*. As usual,  $I$  can be seen, equivalently, as a function from  $HB_s^{\mathcal{S}} \rightarrow \{0, 1\}$ , where: (i)  $I(L) = 1$ , if  $L \in I$ , and (ii)  $I(L) = 0$ , if  $L \notin I$ . Let  $L \in HB_s^{\mathcal{S}}$ . We define: (i)  $I(\sim L) = 1 - I(L)$ , if  $I$  is consistent, and (ii)  $I(\sim L) = 1$ , otherwise.  $I$  also assigns a truth value to special literal  $\mathbf{t}$ . In particular, we define  $I(\mathbf{t}) = 1$ .

Let  $I$  be a simple normal interpretation of  $s$  w.r.t.  $\mathcal{S}$  and let  $L \in HB_s^{\mathcal{S}}$ . It is easy to see that: for all  $L \in HB_s^{\mathcal{S}}$ ,  $I(\neg L) = 1$  implies  $I(\sim L) = 1$  (*coherency*), but not vice-versa.

Let  $\mathcal{S}$  be a modular rule base and let  $s \in \mathcal{S}$ . A *simple extended interpretation* of  $s$  w.r.t.  $\mathcal{S}$  is a set  $I = T \cup \sim F$ , where  $T, F \subseteq HB_s^{\mathcal{S}}$  s.t. either: (i)  $T \cap \neg T = \emptyset$  and  $T \cap F = \emptyset$  (*consistency*), or (ii)  $T = F = HB_s^{\mathcal{S}}$ . If  $I = HB_s^{\mathcal{S}} \cup \sim HB_s^{\mathcal{S}}$  then  $I$  is called *inconsistent*. Otherwise,  $I$  is called *consistent*.

As usual,  $I$  can be seen, equivalently, as a function from  $\text{HB}_s^S \cup \sim\text{HB}_s^S \rightarrow \{0, 1/2, 1\}$ , where: (i)  $I(L) = 1$ , if  $L \in I$ , (ii)  $I(L) = 0$ , if  $L \notin I$  and  $\sim L \in I$ , and (iii)  $I(L) = 1/2$ , if  $L \notin I$  and  $\sim L \notin I$ .  $I$  also assigns truth values to special literals  $\mathbf{t}$  and  $\mathbf{u}$ . In particular, we define  $I(\mathbf{t}) = 1$  and  $I(\mathbf{u}) = 1/2$ .

Let  $S \subseteq \text{HB}_s^S \cup \sim\text{HB}_s^S \cup \{\mathbf{t}, \mathbf{u}\}$ . We define:  $I(S) = \min\{I(L) \mid L \in S\}$ .

Let  $S$  be a modular rule base and let  $s \in S$ . A *normal* (resp. *extended*) interpretation of  $s$  w.r.t.  $S$  is a tuple  $I_s = \langle I_s^d, I_s^o, I_s^c, I_s^n \rangle$ , where  $I_s^x$  is a simple normal (resp. extended) interpretation of  $s$  w.r.t.  $S$  (for  $x \in \{d, o, c, n\}$ ). Intuitively,  $I_s^d, I_s^o, I_s^c$ , and  $I_s^n$  correspond to the definite, open, closed, and normal reasoning modes of  $I_s$ , respectively. A *normal* (resp. *extended*) interpretation of  $S$  is a set  $\mathbf{l} = \{I_s \mid s \in S\}$ , where  $I_s$  is a normal (resp. extended) interpretation of  $s$  w.r.t.  $S$ .

Let  $S$  be a modular rule base. Let  $\mathbf{l} = \{I_s \mid s \in S\}$  and  $\mathbf{j} = \{J_s \mid s \in S\}$  be normal (resp. extended) interpretations of  $S$ . We say that:  $\mathbf{j}$  *extends*  $\mathbf{l}$  w.r.t. *truth* ( $\mathbf{l} \leq_{\mathbf{t}} \mathbf{j}$ ) iff for all  $s \in S$ , for all  $L \in \text{HB}_s^S$ , and for all  $x \in \{d, o, c, n\}$ ,  $I_s^x(L) \leq J_s^x(L)$ .

Before, we define the *normal* and *extended answer sets* of a modular rule base, a few auxiliary definitions are provided. Let  $S$  be a modular rule base and let  $P$  be a logic program. We will denote by  $[P]_S$  the set of rules in  $P$  instantiated over  $\text{HU}_S$ . Below, we define logic program satisfaction, as usual.

**Definition 6 (Logic program satisfaction)** Let  $S$  be a modular rule base, let  $s \in S$ , and let  $I$  be a simple normal (resp. extended) interpretation of  $s$  w.r.t.  $S$ . We say that  $I$  *satisfies* a logic program  $P$  ( $I \models P$ ) iff for all  $r \in [P]_S$ ,  $I(\text{Head}_r) \geq I(\text{Body}_r)$ .  $\square$

Let  $S$  be a modular rule base. For each  $s \in S$ , we define<sup>3</sup> four logic programs that correspond to the four reasoning modes of  $s$ , that is definite, open, closed, and normal.

$$P_s^d = \{r \in P_s \mid \text{mode}_s^d(\text{pred}(\text{Head}_r)) \neq \mathbf{n}\}.$$

$$P_s^o = \{r \in P_s \mid \text{mode}_s^d(\text{pred}(\text{Head}_r)) \in \{\mathbf{o}, \mathbf{c}^+, \mathbf{c}^-\} \cup \{\text{openRules}_s(p) \mid \text{mode}_s^d(p) \in \{\mathbf{o}, \mathbf{c}^+, \mathbf{c}^-\}\}\}.$$

$$P_s^c = \{r \in P_s \mid \text{mode}_s^d(\text{pred}(\text{Head}_r)) \in \{\mathbf{c}^+, \mathbf{c}^-\} \cup \{\text{posClosure}_s(p) \mid \text{mode}_s^d(p) = \mathbf{c}^+\} \cup \{\text{negClosure}_s(p) \mid \text{mode}_s^d(p) = \mathbf{c}^-\}\}.$$

$$P_s^n = \{r \in P_s \mid \text{mode}_s^d(\text{pred}(\text{Head}_r)) = \mathbf{n}\}.$$

It holds:  $(P_s^d \cup P_s^o \cup P_s^c) \cap P_s^n = \emptyset$ .

**Example 7** Consider rule base  $s_1$  of Example 2. It holds:

$$P_{s_1}^d = P_{s_1},$$

$$P_{s_1}^o = P_{s_1} \cup \{-\text{eu:CountryEU}(\text{?x}) \leftarrow \text{geo:Country}(\text{?x}), \sim \text{eu:CountryEU}(\text{?x}), \text{eu:CountryEU}(\text{?x}) \leftarrow \text{geo:Country}(\text{?x}), \sim \neg \text{eu:CountryEU}(\text{?x})\},$$

$$P_{s_1}^c = P_{s_1} \cup \{-\text{eu:CountryEU}(\text{?x}) \leftarrow \text{geo:Country}(\text{?x}), \sim \text{eu:CountryEU}(\text{?x})\}.$$

$$P_{s_1}^n = \{\}. \quad \square$$

<sup>3</sup>Rules  $\text{openRules}_s(p)$ ,  $\text{posClosure}_s(p)$ , and  $\text{negClosure}_s(p)$  are defined in the section that follows Introduction.

The following  $P/S^{\text{mAS}}I$  modulo transformation is used in defining the normal answer sets of a modular rule base. This is actually an adaptation of the  $P/I$  modulo transformation of AS (Gelfond and Lifschitz 1990) (also known as *Gelfond-Lifschitz transformation*).

**Definition 7 (Transformation  $P/S^{\text{mAS}}I$ )**. Let  $S$  be a modular rule base, let  $s \in S$ , and let  $I$  be a simple normal interpretation of  $s$  w.r.t.  $S$ . Let  $P$  be a logic program. The logic program  $P/S^{\text{mAS}}I$  is obtained from  $[P]_S$  as follows:

1. Remove from  $[P]_S$ , all rules that contain in their body a default literal  $\sim L$  s.t.  $I(L) = 1$ .
2. Remove from the body of the remaining rules, any default literal  $\sim L$  s.t.  $I(L) = 0$ .  $\square$

The following  $P/S^{\text{mWFS}}I$  modulo transformation is used in defining the extended answer sets of a modular rule base. This is actually an adaptation of the  $P/I$  modulo transformation of WFSX (Pereira and Alferes 1992) to our framework.

**Definition 8 (Transformation  $P/S^{\text{mWFS}}I$ )**. Let  $S$  be a modular rule base, let  $s \in S$ , and let  $I$  be a simple extended interpretation of  $s$  w.r.t.  $S$ . Let  $P$  be a logic program. The logic program  $P/S^{\text{mWFS}}I$  is obtained from  $[P]_S$  as follows:

1. Remove from  $[P]_S$ , all rules that contain in their body an objective literal  $L$  s.t.  $I(\neg L) = 1$  or a default literal  $\sim L$  s.t.  $I(L) = 1$ .
2. Remove from the body of the remaining rules, any default literal  $\sim L$  s.t.  $I(L) = 0$ .
3. Replace all remaining default literals  $\sim L$  with  $\mathbf{u}$ .  $\square$

**Example 8** Consider the modular rule base  $S$  of Example 2.

$$\text{Let } P = \{ \text{gov:Enter}(\text{?p}) \leftarrow \text{eu:CountryEU}(\text{?c}), \text{sec:citizenOf}(\text{?p}, \text{?c}), \sim \text{sec:Suspect@Nam}_{s_2}(\text{?p}) \}.$$

Consider now the simple *normal* interpretation of  $s_4$  w.r.t.  $S$ ,  $I = \{\text{sec:Suspect@Nam}_{s_2}(\text{Peter})\}$ . Then,

$$P/S^{\text{mAS}}I = \{ \text{gov:Enter}(p) \leftarrow \text{eu:CountryEU}(c), \text{sec:citizenOf}(p, c) \mid p \in \text{HU}_S - \{\text{Peter}\} \text{ and } c \in \text{HU}_S \}.$$

Additionally, consider the simple *extended* interpretation of  $s_4$  w.r.t.  $S$ ,  $I = \{\text{sec:Suspect@Nam}_{s_2}(\text{Peter})\}$ . Then,

$$P/S^{\text{mWFS}}I = \{ \text{gov:Enter}(p) \leftarrow \text{eu:CountryEU}(c), \text{sec:citizenOf}(p, c), \mathbf{u} \mid p \in \text{HU}_S - \{\text{Peter}\} \text{ and } c \in \text{HU}_S \}.$$

Below, we define the minimum model of a modular rule base  $S$  w.r.t. a normal or extended interpretation of  $S$ .

**Definition 9 (Minimum model of a MRB w.r.t. a normal or extended interpretation)** Let  $S$  be a modular rule base and let  $\mathbf{N} = \{N_s \mid s \in S\}$  be a normal (resp. extended) interpretation of  $S$ . The *minimum model* of  $S$  w.r.t.  $\mathbf{N}$ , denoted by  $\text{least}(S, \mathbf{N})$ , is the minimum (w.r.t.  $\leq_{\mathbf{t}}$ ) normal (resp. extended) interpretation of  $S$ ,  $\mathbf{M} = \{M_s \mid s \in S\}$ , such that (for  $s \in S$  and  $x \in \{d, o, c, n\}$ ):

1. For all  $p \in \text{Pred}_s^D$  s.t.  $x > |\text{mode}_s^D(p)|$ , for all  $L \in [p]_S$ :  
 $M_s^x(L) \geq M_s^m(L)$ , where  $m = |\text{mode}_s^D(p)|$ ,
2. For all  $p \in \text{Pred}_s^U$ , and for all  $s' \in \mathcal{S}$  s.t.  $\text{Nam}_{s'} \in \text{Import}_s^S(p)$ :
  - (a) for all  $L \in [p]_S$ :  
 $M_s^x(L) \geq M_{s'}^m(L)$ , where  $m = \text{least}(x, \text{mode}_{s'}^U(p))$ ,
  - (b) for all  $L \in [p@Nam_{s'}]_S$ :  
 $M_s^x(L) \geq M_{s'}^m(\text{simple}(L))$ ,  
where  $m = \text{least}(x, \text{mode}_{s'}^U(p))$ ,
3.  $M_s^x \models P_s^x / \mathcal{S}^{\text{AS}} N_s^x$  (resp.  $M_s^x \models P_s^x / \mathcal{S}^{\text{WFS}} N_s^x$ ).  $\square$

Let  $\mathcal{S}$  be a modular rule base and let  $N = \{N_s \mid s \in \mathcal{S}\}$  be a normal (resp. extended) interpretation of  $\mathcal{S}$ . Additionally, let  $M = \{M_s \mid s \in \mathcal{S}\}$  be the minimum model of  $\mathcal{S}$  w.r.t.  $N$ . Intuitively, Definition 9 expresses that if  $L$  is a literal defined in a rule base  $s$  at reasoning mode  $m$  then the truth value of  $L$ , according to  $M_s$  at reasoning mode  $x \geq |m|$ , is greater than or equal to the truth value of  $L$ , according to  $M_s$  at reasoning mode  $|m|$ . If  $L$  is a literal imported in a rule base  $s$  from a rule base  $s'$  at requesting reasoning mode  $y$  then the truth value of  $L$ , according to  $M_s$  at reasoning mode  $x$ , is greater than or equal to the truth value of  $L$ , according to  $M_{s'}$  at reasoning mode  $m = \text{least}(x, y)$ . Additionally, it holds:  $M_s^x \models P_s^x / \mathcal{S}^{\text{AS}} N_s^x$  (resp.  $M_s^x \models P_s^x / \mathcal{S}^{\text{WFS}} N_s^x$ ).

Below, we adapt the definition of the *Coh* operator in WFSX (Pereira and Alferes 1992) to our framework.

**Definition 10 (Coh operator)** Let  $\mathcal{S}$  be a modular rule base. Additionally, let  $I = \{I_s \mid s \in \mathcal{S}\}$  be an extended interpretation of  $\mathcal{S}$ . We define  $\text{Coh}(I) = \{\text{Coh}(I_s) \mid s \in \mathcal{S}\}$ , where  $\text{Coh}(I_s) = I_s \cup \{\sim L \mid L \in \text{HB}_s^S \text{ and } \neg L \in I_s\}$ .  $\square$

We are now ready to define the normal and extended answer sets of a modular rule base.

**Definition 11 (Normal & extended answer set of a MRB)** Let  $\mathcal{S}$  be a modular rule base and let  $M$  be a normal (resp. extended) interpretation of  $\mathcal{S}$ .  $M$  is a *normal* (resp. *extended*) answer set of  $\mathcal{S}$ , if  $M = \text{least}(\mathcal{S}, M)$  (resp.  $M = \text{Coh}(\text{least}(\mathcal{S}, M))$ ).

We denote the set of normal answer sets of  $\mathcal{S}$  by  $\mathcal{M}^{\text{AS}}(\mathcal{S})$  and the set of extended answer sets of  $\mathcal{S}$  by  $\mathcal{M}^{\text{EAS}}(\mathcal{S})$ .  $\square$

**Example 9** Consider the modular rule base  $\mathcal{S}$  of Example 2. Let  $L = \neg \text{eu}:\text{CountyEU}(\text{Croatia})$ .

For all  $M \in \mathcal{M}^{\text{AS}}(\mathcal{S})$ , it holds:  $M_{s_1}^d(L) = 0$ ,  $M_{s_1}^o(L) \in \{0, 1\}$ , and  $M_{s_1}^c(L) = M_{s_1}^n(L) = 1$ . Additionally, it holds:  $M_{s_4}^d(L) = 0$ ,  $M_{s_4}^o(L) \in \{0, 1\}$ , and  $M_{s_4}^c(L) = M_{s_4}^n(L) \in \{0, 1\}$ . Furthermore, it holds:  $M_{s_4}^n(\text{gov}:\text{Enter}(\text{Anne})) = 1$ ,  $M_{s_4}^n(\text{gov}:\text{Enter}(\text{Boris})) = 1$ , and  $M_{s_4}^n(\text{gov}:\text{Enter}(\text{Peter})) = 0$ .

For all  $M \in \mathcal{M}^{\text{EAS}}(\mathcal{S})$ , it holds:  $M_{s_1}^d(L) = 0$ ,  $M_{s_1}^o(L) \in \{0, 1/2, 1\}$ , and  $M_{s_1}^c(L) = M_{s_1}^n(L) = 1$ . Additionally, it holds:  $M_{s_4}^d(L) = 0$ ,  $M_{s_4}^o(L) \in \{0, 1/2, 1\}$ , and  $M_{s_4}^c(L) = M_{s_4}^n(L) \in \{0, 1/2, 1\}$ . Furthermore, it holds:  $M_{s_4}^n(\text{gov}:\text{Enter}(\text{Anne})) = 1$ ,  $M_{s_4}^n(\text{gov}:\text{Enter}(\text{Boris})) \in \{1/2, 1\}$ , and  $M_{s_4}^n(\text{gov}:\text{Enter}(\text{Peter})) = 0$ .  $\square$

Let  $\mathcal{S}$  be a modular rule base and let  $M$  be a normal (resp. extended) answer set of  $\mathcal{S}$ . Let  $s \in \mathcal{S}$  and let  $L$  be an objective literal, whose predicate  $p$  is defined in  $s$ . The following

proposition relates the truth values of  $L$ , according to the different reasoning modes of  $M_s$ .

**Proposition 1** Let  $\mathcal{S}$  be a modular rule base and let  $M \in \mathcal{M}^{\text{AS}}(\mathcal{S}) \cup \mathcal{M}^{\text{EAS}}(\mathcal{S})$ . Let  $s \in \mathcal{S}$  and let  $p \in \text{Pred}_s^D$ . It holds that:

1. For all  $x \in \{d, o, c, n\}$  and for all  $L \in [p]_S$ :  
 $M_s^d(L) \leq M_s^x(L)$ .
2. For all  $x \geq |\text{mode}_s^D(p)|$  and for all  $L \in [p]_S$ , if  $M_s^x$  is consistent then  $M_s^x(L) = M_s^m(L)$ , where  $m = |\text{mode}_s^D(p)|$ .  $\square$

Let  $\mathcal{S}$  be a modular rule base and let  $M$  be a normal (resp. extended) answer set of  $\mathcal{S}$ . Let  $L$  be a literal imported in a rule base  $s$  from a rule base  $s'$ . Proposition 2 relates the truth value of  $L$  w.r.t.  $M_s$  with the truth value of  $L$  w.r.t.  $M_{s'}$ .

**Proposition 2** Let  $\mathcal{S}$  be a modular rule base and let  $M \in \mathcal{M}^{\text{AS}}(\mathcal{S}) \cup \mathcal{M}^{\text{EAS}}(\mathcal{S})$ . Let  $s \in \mathcal{S}$  and let  $p \in \text{Pred}_s^U$ . Let  $s' \in \mathcal{S}$  s.t.  $\text{Nam}_{s'} \in \text{Import}_s^S(p)$ . Additionally, let  $m = |\text{mode}_s^U(p)|$ , let  $m' = |\text{mode}_{s'}^D(p)|$ , and let  $x \in \{d, o, c, n\}$ . It holds that:

1. For all  $L \in [p]_S$ :  
 $M_s^x(L) \geq M_{s'}^{\text{least}(x, m, m')}(L)$ .
2. If  $p \notin \text{Pred}_s^D$ ,  $|\text{Import}_s^S(p)| = 1$ , and  $M_{s'}^{\text{least}(x, m)}$  is consistent then:  
for all  $L \in [p]_S$ ,  $M_s^x(L) = M_{s'}^{\text{least}(x, m, m')}(L)$ .  $\square$

Let  $\mathcal{S}$  be a modular rule base, let  $M \in \mathcal{M}^{\text{AS}}(\mathcal{S}) \cup \mathcal{M}^{\text{EAS}}(\mathcal{S})$ , and let  $s \in \mathcal{S}$ . The following proposition shows that inconsistency, *local* to  $M_s$  at reasoning mode  $x$ , propagates to reasoning modes greater or equal to  $x$  of other rule bases  $s'$  that import information from  $s$  at requesting reasoning mode  $x$ .

**Proposition 3** Let  $\mathcal{S}$  be a modular rule base and let  $M \in \mathcal{M}^{\text{AS}}(\mathcal{S}) \cup \mathcal{M}^{\text{EAS}}(\mathcal{S})$ . Let  $s \in \mathcal{S}$  and let  $x \in \{d, o, c, n\}$  s.t.  $M_s^x$  is inconsistent. It holds that:

If  $s' \in \mathcal{S}$ ,  $p \in \text{Pred}_{s'}^U$ ,  $\text{Nam}_s \in \text{Import}_{s'}^S(p)$ ,  $\text{mode}_{s'}^U(p) = x$ , and  $y \geq x$  then  $M_{s'}^y$  is inconsistent.  $\square$

Below, we define MWebAS and MWebWFS entailment over a rule base  $s$  w.r.t. a modular rule base  $\mathcal{S}$ .

**Definition 12 (MWebAS & MWebWFS entailment)** Let  $\mathcal{S}$  be a modular rule base and let  $s \in \mathcal{S}$ . Let:

1.  $p \in \text{Pred}_s^D$ ,  $m = |\text{mode}_s^D(p)|$ , and  $L \in [p]_S \cup \sim[p]_S$ , or
2.  $p \in \text{Pred}_s^U - \text{Pred}_s^D$ ,  $m = \text{mode}_s^U(p)$ ,  $L \in [p]_S \cup \sim[p]_S$ , or
3.  $p \in \text{Pred}_s^U$ ,  $m = \text{mode}_s^U(p)$ ,  $\text{Nam}_{s'} \in \text{Import}_s^S(p)$ , and  $L \in [p@Nam_{s'}]_S \cup \sim[p@Nam_{s'}]_S$ .

We say that:

- $s$  entails  $L$  w.r.t.  $\mathcal{S}$  under MWebAS ( $s \models_{\mathcal{S}}^{\text{mAS}} L$ ) iff for all  $M \in \mathcal{M}^{\text{AS}}(\mathcal{S})$ ,  $M_s^m(L) = 1$ .
- $s$  entails  $L$  w.r.t.  $\mathcal{S}$  under MWebWFS ( $s \models_{\mathcal{S}}^{\text{mWFS}} L$ ) iff for all  $M \in \mathcal{M}^{\text{EAS}}(\mathcal{S})$ ,  $M_s^m(L) = 1$ .  $\square$

## Related Work

Initial ideas for our framework and additional motivation are provided in (Damásio et al. 2006). The combination of open-world and closed-world reasoning, in the same framework, is also proposed in (Analyti et al. 2008), where the stable model semantics of Extended RDF (ERDF) ontologies is developed, based on partial logic (Herre, Jaspars, and Wagner 1999). Intuitively, an ERDF ontology is the combination of (i) an ERDF graph  $G$  containing (implicitly existentially quantified) positive and negative information, and (ii) an ERDF program  $P$  containing derivation rules, with possibly all connectives  $\sim, \neg, \supset, \wedge, \vee, \forall, \exists$  in the body of a rule, and strong negation  $\neg$  in the head of a rule. However, modularity issues are not considered there, and local CWAs and OWAs are not declared w.r.t. a context.

A form of local CWA w.r.t. a context is proposed in (Cortés-Calabuig et al. 2005), where the local CWA is applied on the predicates of a *single* data source  $s$ , containing positive facts, only. In this work, a context is a first-order formula over the predicates of  $s$ . The semantics of the proposed local CWA syntax is defined in first-order logic. Rules, strong negation, and modularity issues are not considered, in this work.

An alternative proposal for local CWAs is present in the `dlvhex` system (Eiter et al. 2005). This answer-set programming system has features, like high-order atoms and external atoms, which are very flexible. For instance, assuming that a generic external atom  $KB[C](X)$  is available for querying a concept  $C$  in a knowledge base  $KB$  then a CWA can be stated as follows:  $C'(X) \leftarrow \text{concept}(C), \text{concept}(C'), \text{cwa}(C, C'), o(X), \sim KB[C](X)$ , where  $\text{concept}(C)$  is a predicate which holds for all concepts  $C$ , the predicate  $\text{cwa}(C, C')$  states that  $C'$  is the complement of  $C$  under the closed world assumption, and  $o(X)$  is a predicate that holds for all individuals occurring in  $KB$ .

Flora-2 (Yang, Kifer, and Zhao 2003) is a rule-based object-oriented knowledge base system for reasoning with semantic information on the Web. It is based on F-logic (Kifer, Lausen, and Wu 1995) and supports metaprogramming, non-monotonic multiple inheritance, logical database updates, encapsulation, modules with dynamically assigned content, and qualified literals. Module indicators in qualified literals can be module names or variables that get bound to a module name at run time. In Flora-2, reasoning mode and predicate scope issues are ignored. Additionally, strong negation is not supported. Simple literals appearing in a file, that is loaded to a module, are assumed to be qualified by the module name. The semantics of a modular rule base  $S$  is defined, based on the F-logic semantics (Kifer, Lausen, and Wu 1995) of an equivalent rule base with no modules. In particular, each qualified atom  $\text{subject}[\text{predicate} \rightarrow \text{object}]@Nam_s$  (where  $Nam_s$  is a module name) is translated to  $\text{subject}[\text{predicate}\#Nam_s \rightarrow \text{object}]$ , where  $\text{predicate}\#Nam_s$  is a new predicate name.

TRIPLE (Sintek and Decker 2002) is a rule language for the Semantic Web that supports modules (called, *models* there), qualified literals, and dynamic module transformation. Its syntax is based on F-Logic (Kifer, Lausen, and

**Example 10** Consider the modular rule base  $S$  of Example 2. For  $SEM \in \{\text{mAS}, \text{mWFS}\}$ , it holds:  $s_1 \models_S^{SEM} \neg eu:\text{CountryEU}(\text{Croatia})$ ,  $s_4 \not\models_S^{SEM} \neg eu:\text{CountryEU}(\text{Croatia})$ ,  $s_4 \models_S^{SEM} gov:\text{Enter}(\text{Anne})$ , and  $s_4 \models_S^{SEM} \sim gov:\text{Enter}(\text{Peter})$ . Additionally, it holds  $s_4 \models_S^{\text{mAS}} gov:\text{Enter}(\text{Boris})$ , while  $s_4 \not\models_S^{\text{mWFS}} gov:\text{Enter}(\text{Boris})$ . This is because, MWebAS, in contrast to MWebWFS, supports case-based analysis on the truth values of  $eu:\text{CountryEU}(\text{Croatia})$  and  $\neg eu:\text{CountryEU}(\text{Croatia})$  in rule base  $s_4$ .  $\square$

## Properties of MWebAS & MWebWFS

In this section, we present several properties of the proposed semantics. First, we show that, similarly to AS and WFSX on ELPs, MWebAS is more informative than MWebWFS. However, MWebWFS has better computational properties.

**Proposition 4** Let  $S$  be a modular rule base and let  $s \in S$ . Let  $L \in \text{HB}_s^S \cup \sim \text{HB}_s^S$ . It holds that: if  $s \models_S^{\text{mWFS}} L$  then  $s \models_S^{\text{mAS}} L$ .  $\square$

The following proposition provides the data complexities of MWebAS and MWebWFS semantics. These complexities are the same as the complexities of the answer set (AS) and well-founded semantics with explicit negation (WFSX) on ELPs, respectively. This result follows from the fact that we can define the MWebAS and MWebWFS semantics of a rule base  $s$  w.r.t. a modular rule base  $S$ , through appropriately defined ELPs (not given here due to space limitations).

**Proposition 5** Let  $S$  be a modular rule base and let  $s \in S$ . Let  $L \in \text{HB}_s^S \cup \sim \text{HB}_s^S$ . It holds that: (i) the problem of establishing if  $s \models_S^{\text{mAS}} L$  is data complete for co-NP, and (ii) the problem of establishing if  $s \models_S^{\text{mWFS}} L$  has polynomial data complexity.  $\square$

The following proposition shows that MWebAS and MWebWFS semantics extend AS and WFSX semantics on ELPs, respectively. Let  $P$  be an ELP. We denote by  $C_{SEM}(P)$  the set of literals, obtained from  $P$  under  $SEM \in \{\text{AS}, \text{WFSX}\}$ .

**Proposition 6** Let  $s$  be a rule base s.t. no qualified literal appears in  $P_s$  and for all  $p \in \text{Pred}_s^D$ ,  $\text{mode}_s^D(p) = n$ . Let  $S = \{s\}$ , let  $p \in \text{Pred}_s^D$ , and let  $L \in [p]_S \cup \sim [p]_S$ . It holds that: (i)  $s \models_S^{\text{mAS}} L$  iff  $L \in C_{AS}(P_s)$ , and (ii)  $s \models_S^{\text{mWFS}} L$  iff  $L \in C_{WFSX}(P_s)$ .  $\square$

Let  $S, S'$  be modular rule bases. We say that  $S'$  *expands*  $S$ , if  $S \subseteq S'$ . The following proposition shows that reasoning on the predicates of a modular rule base  $S$  is monotonic under modular rule base expansion, if the set of rule bases from which knowledge about a predicate is imported in any rule base  $s \in S$  stays the same, after the expansion of  $S$ .

**Proposition 7** Let  $S, S'$  be modular rule bases s.t.  $S \subseteq S'$  and for all  $s \in S$  and  $p \in \text{Pred}_s^U$ ,  $\text{Import}_s^S(p) = \text{Import}_s^{S'}(p)$ . Let  $s \in S$ , let  $p \in \text{Pred}_s^U$ , and let  $L \in [p]_S$ . It holds that: if  $s \models_S^{SEM} L$  then  $s \models_{S'}^{SEM} L$ , for  $SEM \in \{\text{mAS}, \text{mWFS}\}$ .  $\square$

Wu 1995) and supports a fragment of RDFS and first-order logic. All variables must be explicitly quantified, either existentially or universally. Arbitrary formulas can be used in the body, while the head of the rules is restricted to atoms or conjunctions of molecules. Module indicators in qualified literals can be module names, variables, or skolem functions, as well as conjunction and difference of module indicators. However, the latter two cases do not add expressive power, as they can be defined, equivalently, through qualified literal conjunctions and the use of weak negation. The semantics of a modular rule base is defined, based on the *well-founded semantics* (WFS) (Gelder, Ross, and Schlipf 1991) of an equivalent logic program. In this work, reasoning mode, predicate scope, and visibility issues are ignored. Additionally, strong negation is not supported.

In (Pontelli, Son, and Baral 2006), a modularity framework for rule bases is proposed and its AS semantics is defined. However, in this work, the dependency graph  $G$  between the rule bases of a modular rule base  $\mathcal{S}$  (formed based on the rule bases' `import` statements) should be acyclic, facilitating distributed evaluation. The answer sets of a module  $s \in \mathcal{S}$  w.r.t.  $\mathcal{S}$  are defined based on the answer sets of the modules that are lower than  $s$  in the dependency graph  $G$ . In this work, reasoning mode and predicate scope issues are ignored. Additionally, strong negation is not supported. It is assumed that exported predicates are provided to any requesting rule base.

Another modularity framework for rule bases is proposed in (Polleres 2006), where weakly negated rule literals should be qualified and depend (directly or indirectly) on qualified literals, only. In this work, reasoning mode, predicate scope, and visibility issues are ignored. Additionally, strong negation is not supported. The *contextually bounded AS* and *contextually bounded WFS* semantics of a modular rule base  $\mathcal{S}$  are defined, through the AS and WFS semantics of an equivalent logic program  $\mathcal{S}_{CB}$ .  $\mathcal{S}_{CB}$  consists of the rules of each rule base  $s \in \mathcal{S}$  (called *contexts*, there) union the rules  $p@Nam_s(t_1, \dots, t_n) \leftarrow Body$ , where  $p(t_1, \dots, t_n) \leftarrow Body$  is a rule defined in a rule base  $s \in \mathcal{S}$ . Another proposal made in (Polleres 2006) is to qualify all simple atoms appearing in a rule base  $s$  by the name of  $s$ . The resulting rules union the original rules of each rule base  $s \in \mathcal{S}$  form a normal logic program  $\mathcal{S}_{CC}$ . The *contextually closed AS* and *contextually closed WFS* semantics of a modular rule base  $\mathcal{S}$  are defined, through the AS and WFS semantics of  $\mathcal{S}_{CC}$ .

Modularity for rule bases is also considered in (Brewka, Roelofsen, and Serafini 2007), where the *contextual AS* and the *contextual WFS* semantics of a modular rule base are defined, model-theoretically. However, in this work, reasoning mode, predicate scope, and visibility issues are ignored. Simple literals appearing in a rule base  $s$  (called *context*, there) are assumed to be qualified by the name of  $s$ . Intuitively, we can say that, if (i) all predicates are defined in normal reasoning mode, (ii) all literals appearing in the body of the rules of the rule bases are qualified, and (iii) predicate scope and visibility issues are ignored, MWebAS and *contextual AS* semantics are equivalent. However, this is not true for MWebWFS and *contextual WFS*. Indeed, in contrast to MWebWFS, *contextual WFS* is not coherent.

Note that all modularity frameworks in (Pontelli, Son, and Baral 2006; Polleres 2006; Brewka, Roelofsen, and Serafini 2007) consider that all weakly negated literals appearing in a rule are qualified and depend (directly and indirectly) on qualified literals, only. Therefore, all frameworks achieve monotonicity of reasoning in the case that a modular rule base is *expanded* with additional rule bases. Our framework achieves also this kind of monotonicity, as expressed in Proposition 7.

Finally, we would like to mention a general framework for multi-context reasoning, proposed in (Brewka and Eiter 2007), that allows to combine arbitrary monotonic and non-monotonic logics. Information flow between the different contexts is achieved through a set of nonmonotonic bridge rules. In this work, several notions for acceptable belief states for the multicontext system are investigated.

## Conclusions

In this paper, we presented a principled framework for modular web rule bases, called MWeb. According to this framework, each predicate  $p$  defined in a rule base  $s$  is characterized by its defining reasoning mode (definite, open, positively closed, negatively closed, or normal), scope (global, local, or internal), and exporting rule base list. Each predicate  $p$  used in a rule base  $s$  is characterized by its requesting reasoning mode and importing rule base list. For valid MWeb modular rule bases  $\mathcal{S}$ , the MWebAS and MWebWFS semantics of each  $s \in \mathcal{S}$  w.r.t.  $\mathcal{S}$  are defined, model-theoretically. These semantics extend the AS (Gelfond and Lifschitz 1990) and WFSX (Pereira and Alferes 1992; Alferes, Damásio, and Pereira 1995) semantics on ELPs, respectively, keeping all of their semantical and computational characteristics.

Our framework supports: (i) local semantics and different points of view, (ii) local closed-world and open-world assumptions, through the contextual CWA and OWA rules, (iii) scoped negation-as-failure and scoped literal evaluation, through the use of qualified literals, the local and internal predicate scopes, and the restricted evaluation of literals in an MWeb modular rule base, (iv) restricted propagation of local inconsistencies, making possible reasoning even in the presence of an inconsistency, local to a web rule base and reasoning mode, and (v) monotonicity of reasoning, in the case that new rule bases are added to the modular rule base, while the importing rule base list of the predicates of the old rule bases remains the same.

In future work, we plan to define a notion of m-equivalent MWeb rule bases such that, for any modular rule base  $\mathcal{S}$  and  $s \in \mathcal{S}$ , if  $s$  is replaced in  $\mathcal{S}$  by an m-equivalent rule base  $s'$  then the MWeb semantics of the other rule bases in  $\mathcal{S}$  will remain unaffected. This is related to the work in (Oikarinen and Janhunnen 2006).

Closing, we would like to mention that the modularity framework, proposed in this paper, has been solely motivated by the needs of the Semantic Web community, which have been discussed in several forums for a long time. To the best of our knowledge, this is the first time that all of the above mentioned issues of modularity for rule bases in the web are combined in a single framework with a precise

semantics. All of these issues have been identified as phase 2 general directions for extensions of the Rule Interchange Framework (RIF). The current proposal is a step in this direction.
